Feasibility of omitting outer (cortical) renorrhaphy during robotic partial nephrectomy - A multi-institutional analysis

Introduction

- Vattikuti Collective Quality Initiative (VCQI):
  - 41 surgeons
  - 14 centers
  - 9 countries
- Reconstruction technique after robotic partial nephrectomy (RPN) has recently been shown to be a modifiable factor with possible impacts on ischemia time, postoperative bleeding, renal function, and incidence of pseudoaneurysms after surgery.
Feasibility of omitting outer (cortical) renorrhaphy during robotic partial nephrectomy - A multi-institutional analysis

- Recent literature comparing single versus double layer (cortical) renorrhaphy stems primarily from single institution studies.
- There are currently no randomized trials.
- Objective: to evaluate the feasibility of omitting cortical renorrhaphy in a multi-institutional setting.

*Standard double layer renorrhaphy technique
Methods

- Inverse probability of treatment weighting (IPTW) was performed to minimize selection bias by adjusting for several preoperative factors.
- Firth correction was applied to the data model to account for center-specific practices.
- Perioperative outcomes were compared between matched cohorts.

Feasibility of omitting outer (cortical) renorrhaphy during robotic partial nephrectomy - A multi-institutional analysis

1453 patients underwent RPN between 2006 and 2018 within the VCQI database

Double layer reconstruction: 1260 patients

Single layer reconstruction: 120 patients
Feasibility of omitting outer (cortical) renorrhaphy during robotic partial nephrectomy - A multi-institutional analysis

</table>

Conclusion:

Omission of cortical renorrhaphy did not significantly improve operative or ischemia time; however, it also had no adverse effect on perioperative outcomes after RPN in a multi-institutional setting.
• Won best poster prize at EAU Barcelona
• Being presented at AUA annual meeting, Chicago as we speak.
